REPORT

The TRK-Fused Gene Is Mutated in Hereditary Motor and Sensory Neuropathy with Proximal Dominant Involvement

Hiroyuki Ishiura,[1] Wataru Sako,[3] Mari Yoshida,[4] Toshitaka Kawarai,[3] Osamu Tanabe,[3,5] Jun Goto,[1] Yuji Takahashi,[1] Hidetoshi Date,[1] Jun Mitsui,[1] Budrul Ahsan,[1] Yaeko Ichikawa,[1] Atsushi Iwata,[1] Hiide Yoshino,[6] Yuishin Izumi,[3] Koji Fujita,[3] Kouji Maeda,[3] Satoshi Goto,[3] Hidetaka Koizumi,[3] Ryoma Morigaki,[3] Masako Ikemura,[7] Naoko Yamauchi,[7] Shigeo Murayama,[8] Garth A. Nicholson,[9] Hidefumi Ito,[10] Gen Sobue,[11] Masanori Nakagawa,[12] Ryuji Kaji,[3,*] and Shoji Tsuji[1,2,13,*]

Hereditary motor and sensory neuropathy with proximal dominant involvement (HMSN-P) is an autosomal-dominant neurodegenerative disorder characterized by widespread fasciculations, proximal-predominant muscle weakness, and atrophy followed by distal sensory involvement. To date, large families affected by HMSN-P have been reported from two different regions in Japan. Linkage and haplotype analyses of two previously reported families and two new families with the use of high-density SNP arrays further defined the minimum candidate region of 3.3 Mb in chromosomal region 3q12. Exome sequencing showed an identical c.854C>T (p.Pro285-Leu) mutation in the TRK-fused gene (*TFG*) in the four families. Detailed haplotype analysis suggested two independent origins of the mutation. Pathological studies of an autopsied patient revealed TFG- and ubiquitin-immunopositive cytoplasmic inclusions in the spinal and cortical motor neurons. Fragmentation of the Golgi apparatus, a frequent finding in amyotrophic lateral sclerosis, was also observed in the motor neurons with inclusion bodies. Moreover, TAR DNA-binding protein 43 kDa (TDP-43)-positive cytoplasmic inclusions were also demonstrated. In cultured cells expressing mutant TFG, cytoplasmic aggregation of TDP-43 was demonstrated. These findings indicate that formation of TFG-containing cytoplasmic inclusions and concomitant mislocalization of TDP-43 underlie motor neuron degeneration in HMSN-P. Pathological overlap of proteinopathies involving TFG and TDP-43 highlights a new pathway leading to motor neuron degeneration.

Hereditary motor and sensory neuropathy with proximal dominant involvement (HMSN-P [MIM 604484]) is an autosomal-dominant disease characterized by predominantly proximal muscle weakness and atrophy followed by distal sensory disturbances.[1] HMSN-P was first described in patients from the Okinawa Islands of Japan, where more than 100 people are estimated to be affected.[2] Two Brazilian HMSN-P-affected families of Okinawan ancestry have also been reported.[3,4]

The disease onset is usually in the 40s and is followed by a slowly progressive course. Painful muscle cramps and abundant fasciculations are observed, particularly in the early stage of the disease. In contrast to the clinical presentations of other hereditary motor and sensory neuropathies (HMSNs) presenting with predominantly distal motor weakness reflecting axonal-length dependence, the clinical presentation of HMSN-P is unique in that it involves proximal predominant weakness with widespread fasciculations resembling those of amyotrophic lateral sclerosis (ALS).[5] Distal sensory loss is accompanied later in the disease course, but the degree of the sensory involvement varies among patients. Neuropathological findings revealed severe neuronal loss and gliosis in the spinal anterior horns and mild neuronal loss and gliosis in the hypoglossal and facial nuclei of the brainstem, which indicates that the primary pathological feature of HMSN-P is a motor neuronopathy involving motor neurons, but not a motor neuropathy involving axons.[1,5] The posterior column, corticospinal tract, and spinocerebellar tract showed loss of myelinated fibers and gliosis. Neuronal loss and gliosis were found in Clarke's nucleus. Dorsal root ganglia showed mild to marked neuronal loss.[1,5] These observations suggest that HMSN-P shares neuropathological findings in part with those observed in familial ALS.[6]

Previous studies on Okinawan kindreds mapped the disease locus to chromosome 3q.[1] Subsequently, we identified two large families (families 1 and 2 in Figure 1A) affected by quite a similar phenotype in the Kansai area of Japan, located in the middle of the main island of Japan and far distant from the Okinawa Islands. We mapped the

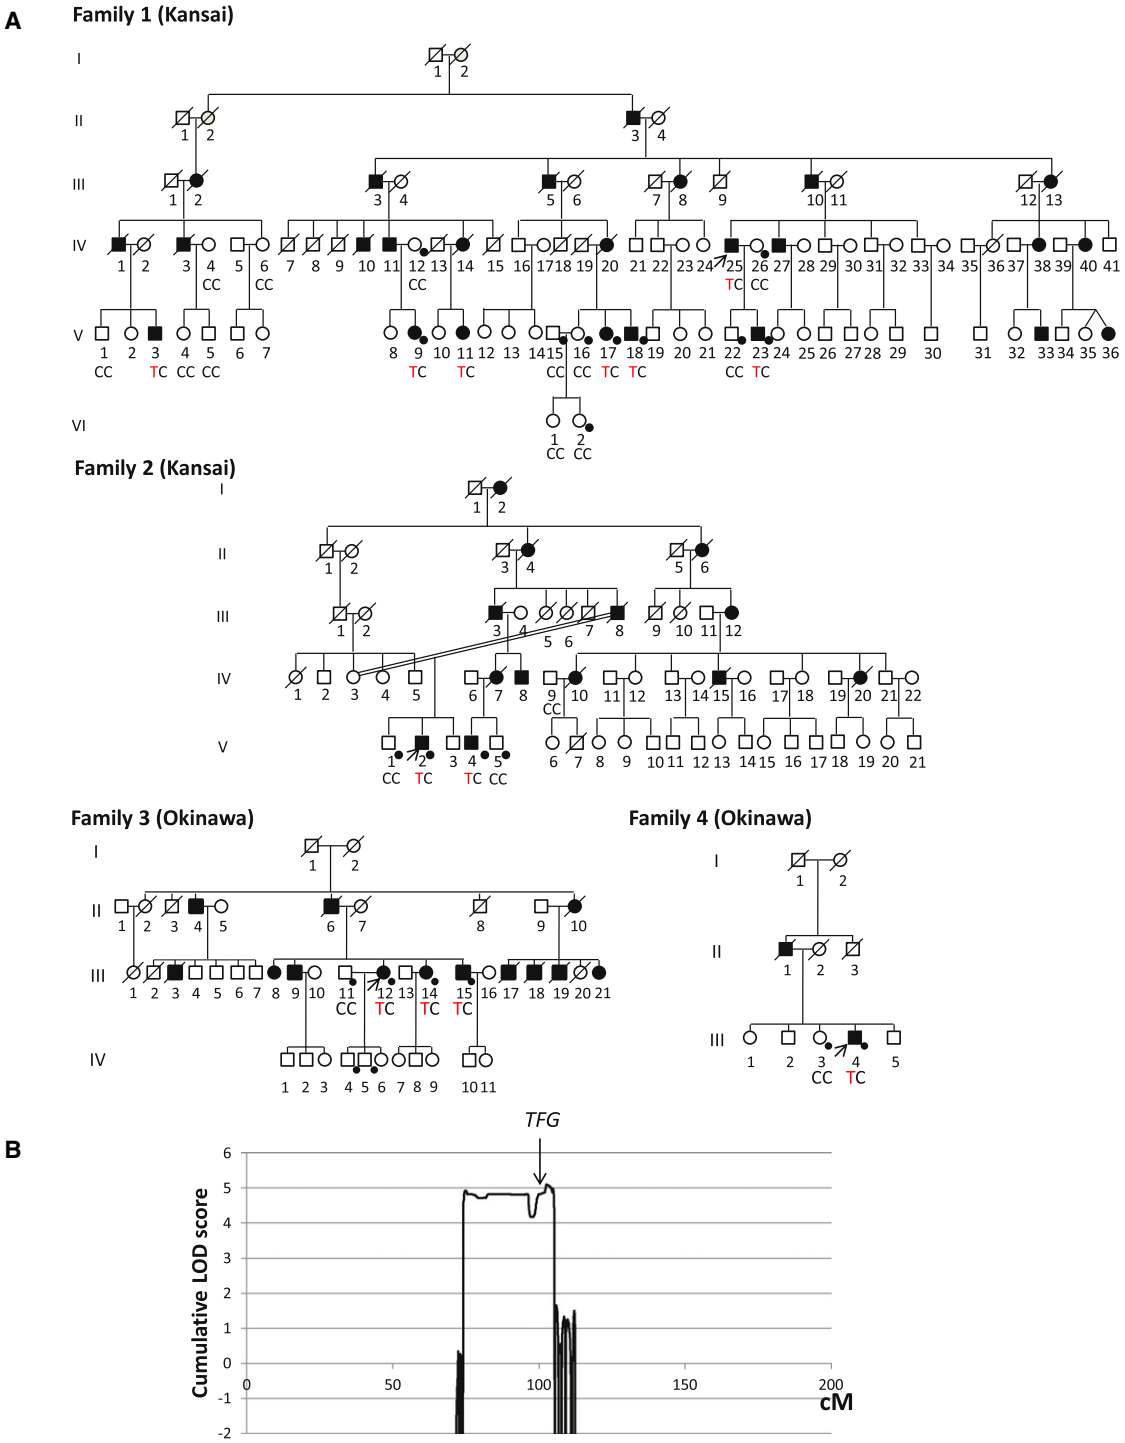

Figure 1. Pedigree Charts and Linkage Analysis
(A) Pedigree charts of families 1 and 2 (Kansai kindreds) and families 3 and 4 (Okinawan kindreds) are shown. Squares and circles indicate males and females, respectively. Affected persons are designated with filled symbols. A diagonal line through a symbol represents a deceased person. A person with an arrow is an index patient. Genotypes of *TFG* c.854 are shown in individuals in whom genomic DNA was analyzed. Individuals genotyped with SNP arrays for linkage analysis and haplotype reconstruction are indicated by dots.
(B) Cumulative parametric multipoint LOD scores on chromosome 3 of all the families are shown.

disease locus to chromosome 3q,[7] overlapping with the previously defined locus, which strongly indicates that these diseases are indeed identical.

In addition to the large Kansai HMSN-P-affected families, we found two new Okinawan HMSN-P-affected families (families 3 and 4 in Figure 1A) in our study. In total, 9 affected and 15 unaffected individuals from the Kansai area and four affected and four unaffected individuals from the Okinawa Islands were enrolled in the study. Written informed consent was obtained from

Table 1. Clinical Characteristics of Patients with HMSN-P from Families 1 and 2 from Kansai and Families 3 and 4 from Okinawa

		Family 3			Family 4
	Families 1 and 2	**III-12**	**III-14**	**III-15**	**III-4**
Age at examination (years)	40s–50s	54	52	50	54
Age at onset (years)	37.5 ± 8	44	40	early 20s	41

The clinical characteristics of the patients from families 1 and 2 were summarized in accordance with the previous studies.[5,6]

all participants. This study was approved by the institutional review boards at the University of Tokyo and the Tokushima University Hospital. Genomic DNA was extracted from peripheral-blood leukocytes or an autopsied brain according to standard procedures.

The clinical presentations of the patients from the four families are summarized in Table 1 and Table S1, available online. Characteristic painful cramps and fasciculations were noted at the initial stage of the disease in all the patients from the four families. Whereas some of the patients showed painful cramps in their 20s, the ages of onset of motor weakness (41.6 ± 2.9 years old) were quite uniform. These patients presented slowly progressive, predominantly proximal weakness and atrophy with diminished tendon reflexes in the lower extremities. Sensory impairment was generally mild. Indeed, one patient (III-4 in family 4) has been diagnosed with very slowly progressive ALS. Although frontotemporal dementia (FTD) is an occasionally observed clinical presentation in patients with ALS, dementia was not observed in these patients. Laboratory tests showed mildly elevated serum creatine kinase levels. Electrophysiological studies showed similar results in all the patients investigated and revealed a decreased number of motor units with abundant positive sharp waves, fibrillation, and fasciculation potentials. Sensory-nerve action potentials of the sural nerve were lost in the later stage of the disease. All these clinical findings were similar to those described in previous reports.[1,3,4]

To further narrow the candidate region, we conducted detailed genotyping by employing the Genome-Wide Human SNP array 6.0 (Affymetrix). Multipoint parametric linkage analysis and haplotype reconstruction were performed with the pipeline software SNP-HiTLink[8] and Allegro v.2[9] (Figure 1A). In addition to the SNP genotyping, we also used newly discovered polymorphic dinucleotide repeats for haplotype comparison (microsatellite marker 1 [MS1], chr3: 101,901,207–101,901,249; and MS2, chr3: 102,157,749–102,157,795 in hg18) around *TFG* (see Table S2 for primer sequences). The genome-wide linkage study revealed only one chromosome 3 region showing a cumulative LOD score exceeding 3.0 (Figure 1B), confirming the result of our previous study.[7] An obligate recombination event was observed between rs4894942 and rs1104964, thus further refining the telomeric boundary of the candidate region in Kansai families (Figure 2A). The Okinawan families (families 3 and 4) shared an extended disease haplotype spanning 3.3 Mb, consistent with a founder effect reported in the Okinawan HMSN-P-affected families,[1] thus defining the 3.3 Mb region as the minimum candidate region.

We then performed exon capture (Sequence Capture Human Exome 2.1 M Array [NimbleGen]) of the index patient from family 3 and subsequent passively parallel sequencing by using two lanes of GAIIx (100 bp single end [Illumina]) and a one-fifth slide of SOLiD 4 (50 bp single end [Life Technologies]). GAIIx and SOLiD4 yielded 2.60 and 2.76 Gb of uniquely mapped reads,[10] respectively. The average coverages were 29.0× and 26.8× in GAIIx and SOLiD4, respectively (Table S3 and Figure S1). In summary, 175,236 single nucleotide variants (SNVs) and 25,987 small insertions/deletions were called.[11] The numbers of exonic and splice-site variants were 14,189 and 127, respectively. In the minimum candidate region of 3.3 Mb, only 11 exonic SNVs were found, and only one was novel (i.e., not found in dbSNP) and nonsynonymous. Direct nucleotide-sequence analysis confirmed the presence of heterozygous SNV c.854C>T (p.Pro285Leu) in TRK-fused gene (*TFG* [NM_006070.5]) in all the patients from families 3 and 4 (Figure 3A and Figure S2[12]). Intriguingly, direct nucleotide-sequence analysis of all *TFG* exons (see Table S4 for primer sequences) of one patient from each of families 1 and 2 from the Kansai area revealed an identical c.854C>T (p.Pro285Leu) *TFG* mutation cosegregating with the disease (Figure 1A and Figure 3A). The base substitution was not observed in 482 Japanese controls (964 chromosomes), dbSNP, the 1000 Genomes Project Database, or the Exome Sequencing Project Database. Pro285 is located in the P/Q-rich domain in the C-terminal region of TFG (Figure 3B) and is evolutionally conserved (Figure 3C). PolyPhen predicts it to be "probably damaging." Because some of the exonic sequences were not sufficiently covered by exome sequencing (i.e., their read depths were no more than 10×) (Figure S1), direct nucleotide-sequence analysis was further conducted for these exonic sequences (Table S5). However, it did not reveal any other novel nonsynonymous variants, confirming that c.854C>T (p.Pro285Leu) is the only mutation exclusively present in the candidate region of 3.3 Mb. All together, we concluded that it was the disease-causing mutation.

Because we found an identical mutation in both Kansai (families 1 and 2) and Okinawan (families 3 and 4) families, we then compared the haplotypes with the c.854C>T (p.Pro285Leu) mutation in the Kansai and Okinawan families in detail. To obtain high-resolution haplotypes, we included custom-made markers, including MS1 and MS2, and new SNVs identified by our exome analysis, in addition to the high-density SNPs used in the linkage analysis. The two Kansai families shared as long as 24.0 Mb of haplotype, and the two Okinawan families shared 3.3 Mb, strongly supporting a common ancestry in each region. When the haplotypes of the Kansai and Okinawan families were compared, it turned out that these families do not share the same haplotype because the markers nearest to *TFG* are discordant at markers 48.5 kb centromeric and 677 bp telomeric to the mutation within a haploblock (Figure 2B). Although the possibility of rare recombination events just distal to the mutation cannot be completely excluded, as suggested by the population-based recombination map (Figure 2B), these findings strongly support the interpretation that the mutations have independent origins and provide further evidence that *TFG* contains the causative mutation for this disease.

Mutational analyses of *TFG* were further conducted in patients with other diseases affecting lower motor neurons (including familial ALS [n = 18], axonal HMSN [n = 26], and hereditary motor neuropathy [n = 3]) and revealed no mutations in *TFG*, indicating that c.854C>T (p.Pro285Leu) in *TFG* is highly specific to HMSN-P.

In this study, we identified in all four families a single variant that appears to have developed on two different haplotypes. The mutation disrupts the PXXP motif, also known as the Src homology 3 (SH3) domain, which might affect protein-protein interactions. In addition, substitution of leucine for proline is expected to markedly alter the protein's secondary structure, which might substantially compromise the physiological functions of TFG.

By employing the primers shown in Table S6, we obtained full-length cDNAs by PCR amplification of the cDNAs prepared from a cDNA library of the human fetal brain (Clontech). During this process, four species of cDNA were identified (Figure S3A). To determine the relative abundance of these cDNA species, we used the primers shown in Table S7 to conduct fragment analysis of the RT-PCR products obtained from RNAs extracted from various tissues; these primers were designed to discriminate four cDNA species on the basis of the size of the PCR products. The analysis revealed that TFG is ubiquitously expressed, including in the spinal cord and dorsal root ganglia, which are the affected sites of HMSN-P (Figure S3B).

Neuropathological studies were performed in a *TFG*-mutation-positive patient (IV-25 in family 1) who died of

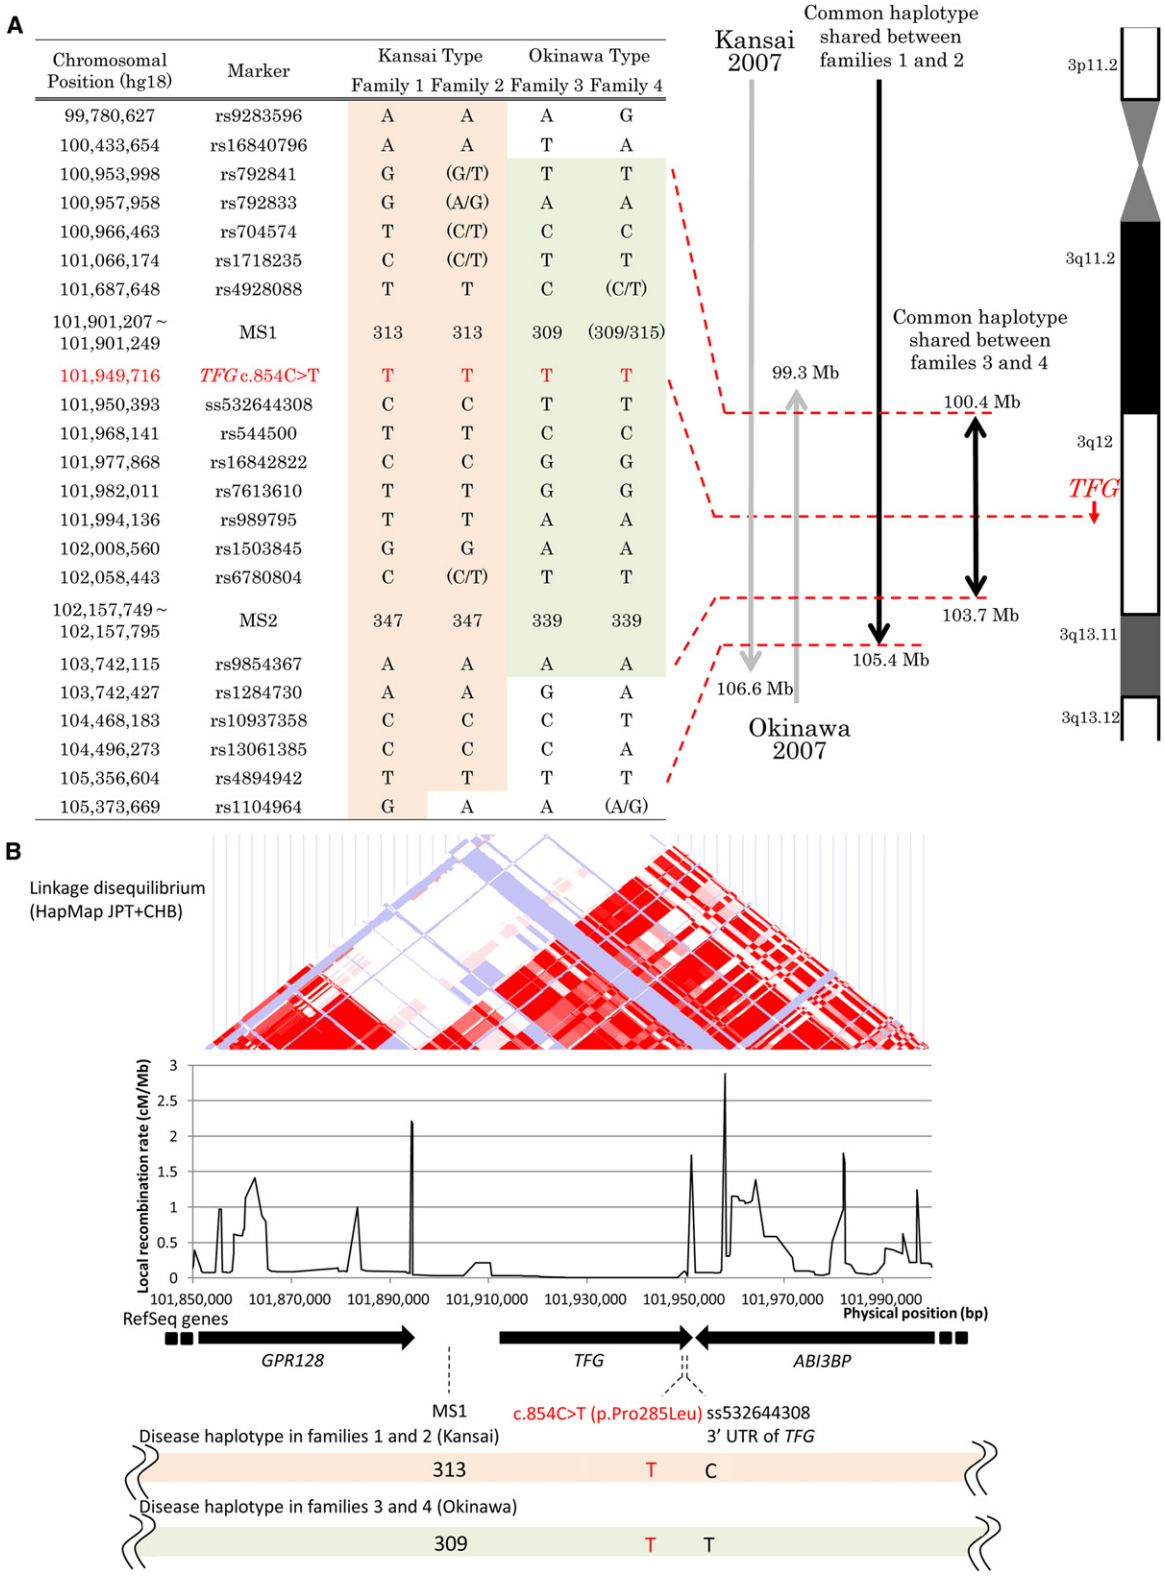

Figure 2. Haplotype Analysis and Minimum Candidate Region of HMSN-P
(A) Haplotypes were reconstructed for all the families with the use of SNP array data and microsatellite markers. Previously reported candidate regions are shown as "Kansai 2007" and "Okinawa 2007."[1,6] Because families 1 and 2 are distantly related, an extended shared common haplotype was observed on chromosome 3, as indicated by a previous study.[6] A reassessment of linkage analysis with high-density SNP markers revealed a recombination between rs4894942 and rs1104964 in family 2, thus refining the telomeric boundary of the candidate region in Kansai families (designated as "Common haplotype shared between families 1 and 2). Furthermore, a shared common haplotype (3.3 Mb with boundaries at rs16840796 and rs1284730) between families 3 and 4 was found, defining the minimum candidate region.

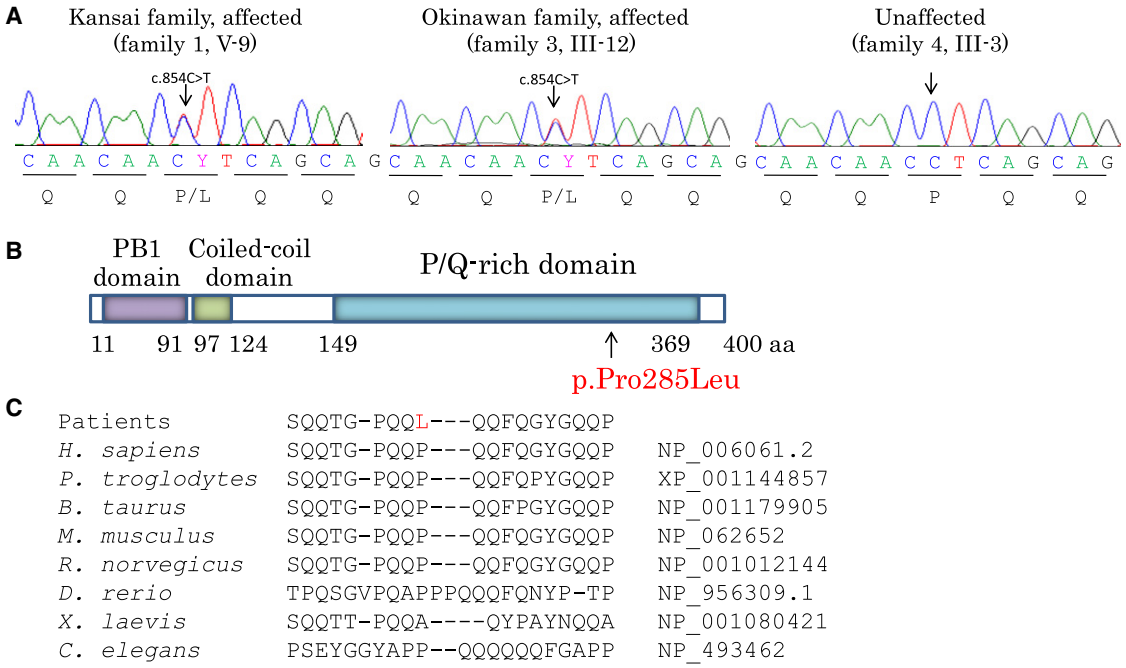

Figure 3. Identification of Causative Mutation

(A) Exome sequencing revealed that only one novel nonsynonymous variant is located within the minimum candidate region. Direct nucleotide-sequence analysis confirmed the mutation, c.854C>T (p.Pro285Leu), in *TFG* in both Kansai and Okinawan families. The mutation cosegregated with the disease (Figure 1A).

(B) Schematic representation of TFG isoform 1. The alteration (p.Pro285Leu) detected in this study is shown below.

(C) Cross-species homology search of the partial TFG amino acid sequence containing the p.Pro285Leu alteration revealed that Pro285 is evolutionally conserved among species.

pneumonia at 67 years of age.[5] Immunohistochemical observations employing a TFG antibody (Table S8) revealed fine granular immunostaining of TFG in the cytoplasm of motor neurons in the spinal cord of neurologically normal controls (n = 3; age at death = 58.7 ± 19.6 years old) (Figure 4A). In the HMSN-P patient, in contrast, TFG-immunopositive inclusion bodies were detected in the motor neurons of the facial, hypoglossal, and abducens nuclei and the spinal cord, as well as in the sensory neurons of the dorsal root ganglia, but were not detected in glial cells (Figures 4B–4D). A small number of cortical neurons in the precentral gyrus also showed TFG-immunopositive inclusion bodies (Figure 4E). Serial sections stained with antibodies against ubiquitin or TFG (Figure 4F) and double immunofluorescence staining (Figure 4G) demonstrated that TFG-immunopositive inclusions colocalized with ubiquitin deposition. Inclusion bodies were immunopositive for optineurin in motor neurons of the brainstem nuclei and the anterior horn of the spinal cord,[5] as well as in sensory neurons of the dorsal root ganglia (data not shown). These data strongly indicate that HMSN-P is a proteinopathy involving TFG.

Because HMSN-P and ALS share some clinical characteristics, we then examined whether neuropathological findings of HMSN-P shared cardinal features with those of sporadic ALS.[13–16] Immunohistochemistry with a TDP-43 antibody revealed skein-like inclusions in the remaining motor neurons of the abducens nucleus and the anterior horn of the lumbar cord (Figures 4H–4I). Phosphorylated TDP-43-positive inclusions were also identified in neurons of the anterior horn of the cervical cord and Clarke's nucleus (Figures 4J–4K). In contrast, TFG immunostaining of spinal-cord specimens from four patients with sporadic ALS (their age at death was 72.3 ± 7.4 years old) revealed no pathological staining in the motor neurons (data not shown). Double immunofluorescence staining revealed that many of the TFG-immunopositive round inclusions in the HSMN-P patient were negative for TDP-43 (Figure 4L), whereas a small number of inclusions were positive for both TFG and TDP-43 (Figure 4M). In addition, to investigate morphological Golgi-apparatus changes, which have recently been found in motor neurons of autopsied tissues of ALS patients,[17] we conducted immunohistochemical analysis by using

(B) Disease haplotypes in the Kansai and Okinawan kindreds are indicated below. Local recombination rates, RefSeq genes, and the linkage disequilibrium map from HapMap JPT (Japanese in Tokyo, Japan) and CHB (Han Chinese in Beijing, China) samples are shown above the disease haplotypes. When disease haplotypes of the Kansai and Okinawan kindreds are compared, the markers nearest to *TFG* are discordant at markers 48.5 kb centromeric and 677 bp telomeric to the mutation within a haploblock, strongly supporting the interpretation that the mutations have independent origins.

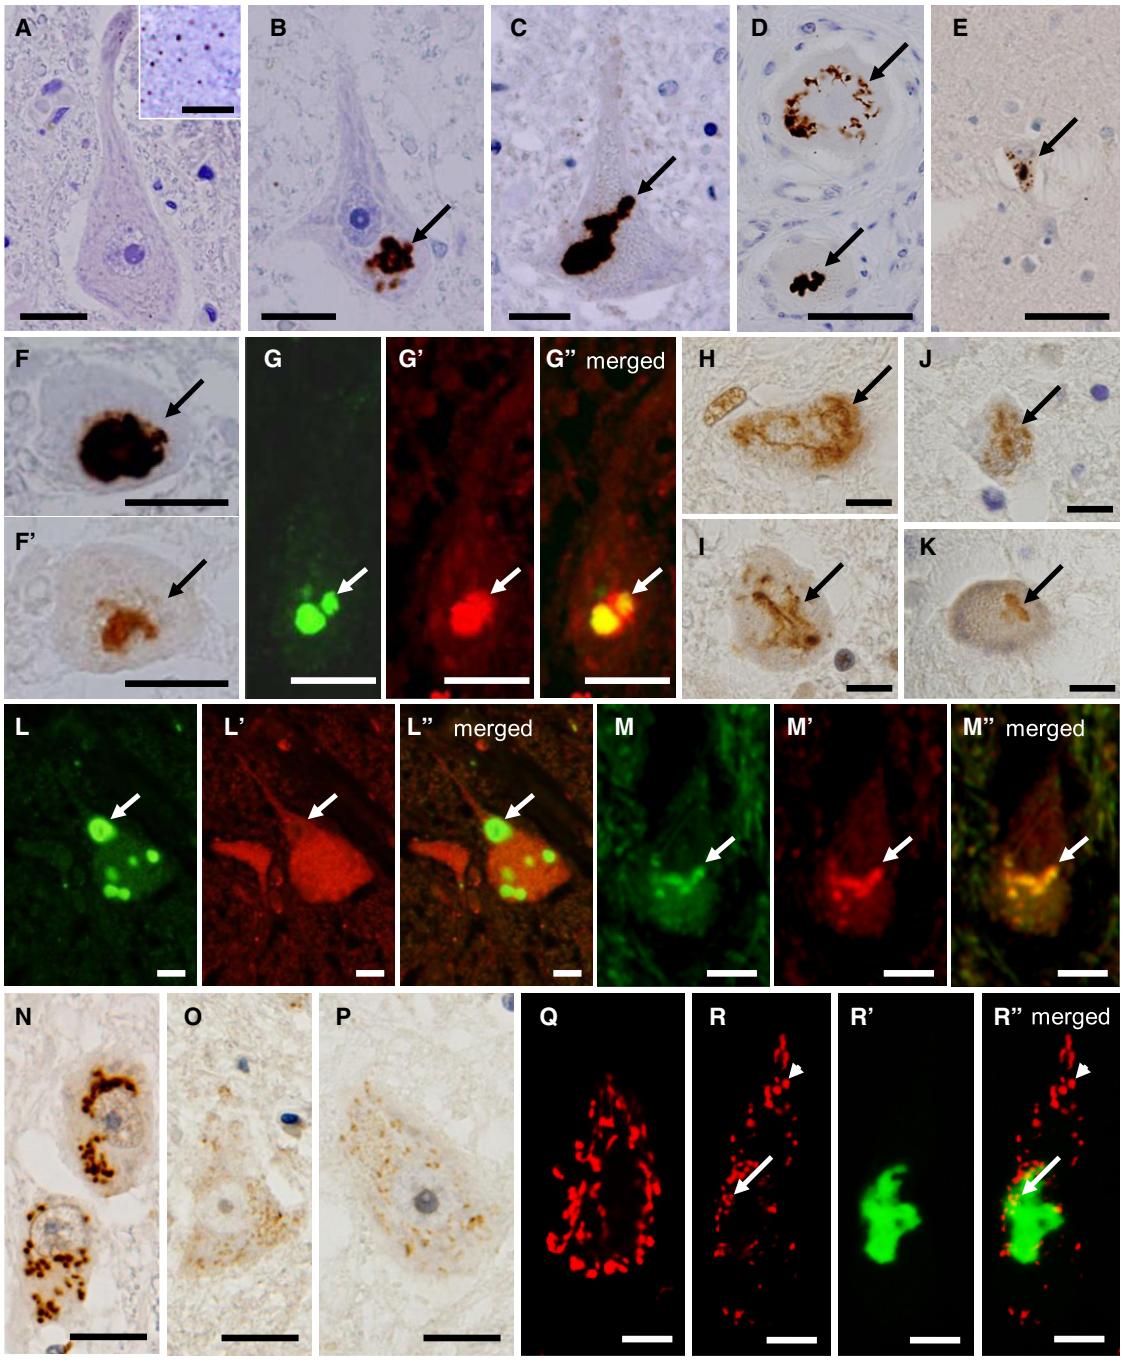

Figure 4. TFG-Related Neuropathological Findings

(A) TFG immunostaining (with hematoxylin counterstaining) of a motor neuron in the spinal cord of a neurologically normal control. A high-power magnified photomicrograph (inset) shows fine granular staining of TFG in the cytoplasm. The scale bars represent 20 μm (main panel) and 10 μm (inset).

(B–E) TFG-immunopositive inclusions of the neurons (with hematoxylin counterstaining) in the hypoglossal nucleus (B), anterior horn of the spinal cord (C), dorsal root ganglion (D, arrows), and motor cortex (E, arrow) of the patient with the *TFG* mutation. The scale bars represent 20 μm (B–D) and 50 μm (E).

(F and F′) Serial section analysis of the facial nucleus motor neuron showing an inclusion body colabeled for TFG (F) and ubiquitin (F′). The scale bars represent 20 μm.

(G–G″) Double immunofluorescence microscopy confirming colocalization of TFG (green) and ubiquitin (red) in an inclusion body of a motor neuron in the hypoglossal nucleus. The scale bars represent 20 μm.

(H and I) TDP-43-positive skein-like inclusions in the motor neurons of the abducens nucleus (H) and anterior horn of the lumbar cord (I). The scale bars represent 20 μm.

(J and K) Phosporylated TDP-43-positive inclusion bodies in the cervical anterior horn (J) and Clarke's nucleus (K). The scale bars represent 20 μm.

(L–L″) Round inclusions (arrows) positive for TFG (green) but negative for TDP-43 (red). The scale bars represent 20 μm.

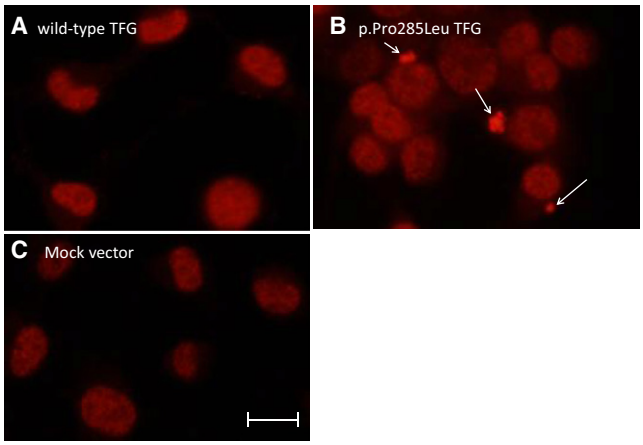

Figure 5. Formation of Cytoplasmic TDP-43 Aggregation Bodies in Cells Stably Expressing Mutant p.Pro285Leu TFG
The coding sequence of *TFG* cDNA was subcloned into pBluescript (Stratagene). After site-directed mutagenesis with a primer pair shown in Table S9, the mutant cDNAs were cloned into the BamHI and XhoI sites of pcDNA3 (Life Technologies). Stable cell lines were established by Lipofectamine (Life Technologies) transfection according to the manufacturer's instructions. Established cell lines were cultured under the ordinary cell-culture conditions (37°C and 5% CO_2) for 5–6 days and were subjected to immunocytochemical analyses. Neuro-2a cells stably expressing wild-type TFG (A), mutant TFG (p.Pro285Leu) (B), and a mock vector (C) are shown. TDP-43-immunopositive cytoplasmic inclusions are absent in the cells stably expressing wild-type TFG or the mock vector (A and C); however, TDP-43-immunopositive cytoplasmic inclusions were exclusively demonstrated in cells stably expressing mutant TFG (p.Pro285Leu), as indicated by arrows (B). Similar results were obtained with HEK 293 cells (not shown). Scale bars represent 10 μm.

a TGN46 antibody. It revealed that the Golgi apparatus was fragmented in approximately 70% of the remaining motor neurons in the lumbar anterior horn. The fragmentation of the Golgi apparatus was prominent near TFG-positive inclusion bodies (Figures 4N–4R). In summary, we found abnormal TDP-43-immunopositive inclusions in the cytoplasm of motor neurons, as well as fragmentation of the Golgi apparatus in HMSN-P, confirming the overlapping neuropathological features between HMSN-P and sporadic ALS.

To further investigate the effect of mutant TFG in cultured cells, stable cell lines expressing wild-type and mutant TFG (p.Pro285Leu) were established from neuro-2a and human embryonic kidney (HEK) 293 cells as previously described.[18] Established cell lines were cultured under the ordinary cell-culture conditions (37°C and 5% CO_2) for 5–6 days and were subjected to immunocytochemical analyses. The neuro-2a cells stably expressing wild-type or mutant TFG demonstrated no distinct difference in the distribution of endogenous TFG, FUS, or OPTN (data not shown). In contrast, cytoplasmic inclusions containing endogenous TDP-43 were exclusively observed in the neuro-2a cells stably expressing untagged mutant TFG, but not in those expressing wild-type TFG (Figure 5). Similar data were obtained from HEK 293 cells (data not shown). Thus, the expression of mutant TFG leads to mislocalization and inclusion-body formation of TDP-43 in cultured cells.

TFG was originally identified as a part of fusion oncoproteins (NTRK1-T3 in papillary thyroid carcinoma,[19] TFG-ALK in anaplastic large cell lymphoma,[20] and TFG/NOR1 in extraskeletal myxoid chondrosarcoma[21]), where the N-terminal portions of TFG are fused to the C terminus of tyrosine kinases or a superfamily of steroid-thyroid hormone-retinoid receptors acting as a transcriptional activator leading to the formation of oncogenic products. Very recently, TFG-1, a homolog of TFG in *Caenorhabditis elegans*, and TFG have been discovered to localize in endoplasmic-reticulum exit sites. TFG-1 acts in a hexameric form that binds the scaffolding protein Sec16 complex assembly and plays an important role in protein secretion with COPII-coated vesicles.[22] It is noteworthy that mutations in genes involved in vesicle trafficking[23,24] (such genes include *VAPB*, *CHMP2B*, *alsin*, *FIG4*, *VPS33B*, *PIP5K1C*, and *ERBB3*) cause motor neuron diseases, emphasizing the role of vesicle trafficking in motor neuron diseases. Thus, altered vesicle trafficking due to the *TFG* mutation might be involved in the motor neuron degeneration in HMSN-P. The presence of TFG-immunopositive inclusions in motor neurons raises the possibility that mutant TFG results in the misfolding and formation of cytoplasmic aggregate bodies, as well as altered vesicle trafficking.

An intriguing neuropathological finding is TDP-43-positive cytoplasmic inclusions in the motor neurons; these inclusions have recently been established as the fundamental neuropathological findings in ALS.[13,14] Of note, expression of mutant, but not wild-type, TFG in cultured cells led to the formation of TDP-43-containing cytoplasmic aggregation. These observations are similar

(M–M″) An inclusion immunopositive for both TFG (green) and TDP-43 (red) is observed in a small number of neurons. The scale bars represent 20 μm.
(N) Normal Golgi apparatus in the neurons of the intact thoracic intermediolateral nucleus. The scale bar represents 20 μm.
(O and P) Fragmentation of the Golgi apparatus with small, round, and disconnected profiles in the affected motor neurons of the lumbar anterior horn. The scale bars represent 20 μm.
(Q–R″) Immunohistochemical observations of the Golgi apparatus and TFG-immunopositive inclusions employing antibodies against TGN46 (red) and TFG (green), respectively. The scale bars represent 10 μm.
(Q) Normal size and distribution (red) in a motor neuron without inclusions.
(R–R″) The Golgi apparatus was fragmented into various sizes and reduced in number in the lumbar anterior horn motor neuron with TFG-positive inclusions (green). The fragmentation predominates near the inclusion (arrow), whereas the Golgi apparatuses distant from the inclusion showed nearly normal patterns (arrow head).

to what has been described for ALS, where TDP-43 is mislocalized from the normally localized nucleus to the cytoplasm with concomitant cytoplasmic inclusions. Cytoplasmic TDP-43 accumulation and inclusion formation have also been observed in motor neurons in familial ALS with mutations in *VAPB* (MIM 608627) or *CHMP2B* (MIM 600795).[25,26] Furthermore, TDP-43 pathology has been demonstrated in transgenic mice expressing mutant VAPB.[27] Although the mechanisms of mislocalization of TDP-43 remain to be elucidated, these observations suggest connections between alteration of vesicle trafficking and mislocalization of TDP-43. Thus, common pathophysiologic mechanisms might underlie motor neuron degenerations involving vesicle trafficking including TFG, as well as VAPB and CHMP2B. Because TDP-43 is an RNA-binding protein, RNA dysregulation has been suggested to play important roles in the TDP43-mediated neurodegeneration.[28] Furthermore, recent discovery of hexanucleotide repeat expansions in *C9ORF72* in familial and sporadic ALS/FTD (MIM 105550)[29,30] emphasizes the RNA-mediated toxicities as the causal mechanisms of neurodegeneration. Observations of TDP-43-positive cytoplasmic inclusions in the motor neurons of the patient with HMSN-P raise the possibility that RNA-mediated mechanisms might also be involved in motor neuron degeneration in HMSN-P.

In summary, we have found that *TFG* mutations cause HMSN-P. The presence of TFG/ubiquitin- and/or TDP-43-immunopositive cytoplasmic inclusions in motor neurons and cytosolic aggregation composed of TDP-43 in cultured cells expressing mutant TFG indicate a novel pathway of motor neuron death.

Supplemental Data

Supplemental Data include three figures and nine tables and can be found with this article online at http://www.cell.com/AJHG/.

Acknowledgments

The authors thank the families for participating in the study. We also thank the doctors who obtained clinical information of the patients. This work was supported in part by Grants-in-Aid for Scientific Research on Innovative Areas (22129002); the Global Centers of Excellence Program; the Integrated Database Project; Scientific Research (A) (B21406026) and Challenging Exploratory Research (23659458) from the Ministry of Education, Culture, Sports, Science, and Technology of Japan; a Grant-in-Aid for Research on Intractable Diseases and Comprehensive Research on Disability Health and Welfare from the Ministry of Health, Labour, and Welfare, Japan; Grants-in-Aid from the Research Committee of CNS Degenerative Diseases; the Ministry of Health, Labour, and Welfare of Japan; the Charcot-Marie-Tooth Association; and the National Medical Research Council of Australia. H.I. was supported by a Research Fellowship from the Japan Society for the Promotion of Science for Young Scientists. We also thank S. Ogawa (Cancer Genomics Project, The University of Tokyo) for his kind help in the analyses employing GAIIx and SOLiD4.
